INTRODUCTION

Increasingly, we can see the unique properties of mechanical vibration and ultrasonic waves put to use in many ways. And the single most important key to the effective monitoring or use of vibration is the transducer. Today's transducers are called on for standards of performance that are higher than ever before.

For best results in any application, the piezoelectric materials in the transducer should be selected with the specific use in mind. This catalog contains a wealth of information to help you evaluate transducer characteristics.

And when it comes to the materials themselves, look to TOKIN's NEPEC® NPM piezoelectric ceramics. Using zircon and lead titanate as the main components, NEPEC materials have a wealth of features:
1) A wide selection range, especially for mechanical characteristics and degree of electromechanical coupling.
2) High stability against temperature and humidity variations and aging.
3) Remarkably fine ceramics that can be machined into a variety of sizes and shapes.
4) Excellent resistance to voltage, permitting transducers with polarization in any direction.
5) A wide range of potential uses.

This catalog describes TOKIN's standard piezoelectric ceramics, and it also describes TOKIN's line of transducers. If you cannot find the desired material characteristics or transducer for your application in these pages, please contact us directly; our engineering staff can work with you to develop materials for your purpose.

Piezoelectric Ceramics

OPERATING PRINCIPLES OF PIEZOELECTRIC CERAMICS

When considered at the crystal level, a piezoelectric ceramics has the following properties.

A piezoelectric material possesses a perovskite crystalline structure. Lead zirconate titanate PbZr\(_{0.5}\)-PbTi\(_{0.5}\) (abbreviated to PZT) which is the primary component of the piezoelectric material is used as an example for explanation.

The crystalline structure of PZT becomes cubic (a cube) above a certain temperature known as the Curie temperature (Tc) (see Fig. 1-1a). In the cubic structure, three crystallographic axes have the same length (a = b = c), and all the angles between the crystallographic axes are 90° (\(a = \beta = \gamma = 90°\)). A positively charged Zr ion or Ti ion is centered on the lattice. The crystal is electrically balanced at this time, and therefore no electrical polarization arises in the crystal.

However, below the Curie temperature, the crystal structure becomes tetragonal (or assumes a rectangular-parallelepiped shape) or rhomboid. In the tetragonal structure, the c axis is longer than the other two axes (a = b \(\neq\) c), and all the angles between the axes are 90°. On the other hand, in the rhomboid structure, the three axes have the same length (a = b = c), and the angles between the axes are not 90° (\(a = \beta = \gamma \neq 90°\)).

A typical tetragonal structure will now be described. Below the Curie temperature, the positively charged Zr ion or Ti ion shift from the center. As a result of this, the c axis of the crystal becomes longer, and the resulting electrical imbalance brings about a dipole moment. The Zr ion or Ti ion has equivalent energy even when shifted to any position along the six axes in the crystal (Fig. 1-1b).

If an external electric field is applied to this tetragonal crystal, the Zr ion or Ti ion shift in the direction of the electric field. Even if the electric field is eliminated, the Zr ion or Ti ion do not return to their original positions and stay aligned in the direction of the electric field. As a result of this, the direction of the longer axis changes (Fig. 1-1c). This phenomenon is called 90° inversion. As a matter of course, 180° inversion may also occur. However, in this case, the direction of the long axis remains unchanged.

When an external electric field is applied to the crystal, the Zr ion or Ti ion are attracted to the negative side of the electric field, whereas O (oxygen) ions are attracted to the positive side, resulting in a longer crystal (Fig. 1-1d). Specifically, the application of the external electric field brings the displacement (expansion) of the crystalline lattice. Variations in the length of the crystal can be obtained as displacement in the form of voltage. This is one of the principal factors with respect to the operating principles of the piezoelectric ceramics.
Below the Curie point, as viewed from a macroscopic viewpoint, that is, as considered at the crystal grain level, bounded areas (domains) where the Zr ion or Ti ion of the atoms are aligned in the same direction are generated (Fig. 1-2a). The domains have large Zr ion or Ti ion. The spontaneous polarization cancels each other out, and the Zr ion or Ti ion of the piezoelectric ceramic element as a whole is zero. Such a state is called a nonpolarized state.

If an electric field is applied to the nonpolarized piezoelectric ceramic element, the directions of the Zr ion or Ti ion of the domains are aligned in the direction close to the electric field as a result of the shift of the Zr ion or Ti ion. This phenomenon is called polarization. As a result of this, the length of the piezoelectric ceramic element becomes longer in the direction of the electric field (Fig. 1-2b).

Even if the electric field is eliminated, the length of the piezoelectric ceramic element does not return to its original length in the nonpolarized state as a result of the 90° inversion of the Zr ion or Ti ion. The variation in the length of the element is called residual polarization (Fig. 1-2c). The element is most stable in the nonpolarized state, from the viewpoint of energy. For this reason, the polarization is gradually lost if the element is stored for a long period of time, and the element finally returns to the nonpolarized state.

Some of the Zr ion or Ti ion which are inverted by 90° while the electric field is applied to the element become unstable, in terms of energy, as a result of the influence of the neighboring domains at the moment the electric field is eliminated, and they return to their original positions (their positions when the element was nonpolarized). In other words, when the electric field (a voltage) is applied to the piezoelectric ceramic element, the element becomes longer in the direction of the electric field. On the other hand, when the electric field (a voltage) is eliminated, the element returns to its original length. This variation in the length of the element is the displacement that can be obtained in the form of voltage. The variation in the length of the element is another element of the principal factors with respect to the operating principles of the piezoelectric ceramics.

\[ P_s \]

\[ P_r = \Sigma P_s \]
Ceramic Design Information

Outline

A piezoelectric material responds mechanically when voltage is applied, and conversely, generates a voltage in response to a mechanical change.

To create piezoelectric ceramics, polycrystalline ceramics are fired and baked at a high temperature. Then electrodes are mounted and a DC field applied in order to polarize the ceramic material; once polarized, the material exhibits piezoelectric properties, allowing it to be used as a piezoelectric ceramic transducer. These transducers are also called electrostriction transducers, since ceramic crystals are deformed by electricity.

Barium titanate and lead zirconate are the most popular piezoelectric ceramics. In addition, TOKIN also uses a variety of other materials, including conventional lead zirconate.

This results in piezoelectric materials that can be used in a wide variety of applications: those that use the piezoelectric effect (such as igniters and pickups), those that utilize resonance (e.g., filters), and those that utilize the electrostrictive effect (such as piezoelectric buzzers and displacement elements).

In addition to barium titanate and lead zirconate, popular as piezoelectric ceramics, TOKIN offers multi-component solid ceramics developed from conventional lead zirconate ceramics. They meet a wide range of specifications for a wide range of applications. The main applications include: those that use the piezoelectric effect (such as sensors and pickups), those that utilize resonance (such as transducers for ultrasonic motors and cleaning equipments), and those that utilize the electrostrictive effect (such as piezoelectric sound elements and displacement elements). In addition, they can be used as ultrasonic vibrators and transducers.
Evaluation of Transducer Characteristics

TOKIN evaluates the characteristics of transducer materials based on a number of parameters.

1) Resonant Frequency

When an AC voltage is applied to the transducer and frequency $f$ is varied to be in agreement with the natural frequency of the transducer, it vibrates very violently. This frequency is called resonance frequency $f_r$.

A constant voltage circuit or a low voltage circuit was used for measurement of the resonance and anti-resonance frequencies. These frequencies can be measured easily with an impedance analyzer such as the 4294A of Agilent Technologies.

Resonance frequency $f_r$ obtained from the equivalent circuit near the resonance frequency and anti-resonance frequency $f_a$ can be expressed by the following equations:

$$f_r = \frac{1}{2\pi\sqrt{L_1C_1}}$$

$$f_a = \frac{1}{2\pi\sqrt{\frac{L_1C_1}{C_1 + C_0}}}$$

Resonant frequency $f_r$ can be defined in a number of different ways, depending on the mechanical structure and oscillation of the transducer.

a) Radial vibration

$$f_r = \frac{N}{D \text{[Hz]}} \quad \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdots \cdot (1)$$

Radial vibration is in the direction of the arrows. The coefficient of electromechanical coupling for this type of vibration is called $K_r$. 
b) **Lengthwise vibration**

\[ fr = \frac{N_2}{l} \text{[Hz]} \]  \hspace{1cm} (2)

The direction of vibration is perpendicular to the polarization direction; it is a simple vibration in one plane only. The coefficient of electromechanical coupling is known as \( K_{31} \).

c) **Longitudinal vibration**

\[ fr = \frac{N_3}{l} \text{[Hz]} \]  \hspace{1cm} (3)

The directions of polarization and vibration are the same, vibration is simple vibration. The electromechanical coupling coefficient is known as \( K_{33} \).

d) **Thickness vibration**

\[ fr = \frac{N_4}{t} \text{[Hz]} \]  \hspace{1cm} (4)

Here, thickness is small compared with the area of the radiation plane; the effect of vibration is the same as that of longitudinal vibration. Generally, vibration is in two directions, and discrimination can be made between the two. The electromechanical coupling coefficient for this type of vibration is called \( K_t \).

e) **Shear vibration**

\[ fr = \frac{N_5}{t} \text{[Hz]} \]  \hspace{1cm} (5)

The direction of vibration is the same as the polarization direction. Orientation of the drive field direction is perpendicular to it. A drive electrode is located perpendicular to the direction of polarization. The electromechanical coupling coefficient is expressed by \( K_{15} \).

The coefficient of electromechanical coupling represents the mechanical energy accumulated in a ceramic or crystal; it is related to the total electrical input. This coefficient \( k \) can be calculated for each individual vibration mode by using the resonant (\( fr \) or \( fm \)) and antiresonant frequencies (\( fa \) or \( fn \)) and the applicable formula shown here:

\[ K_r = \left( 0.395 \times \frac{fr}{fa} + 0.574 \right)^{-1} \]  \hspace{1cm} (6)

\[ K_{31} = \frac{r}{\sqrt{r - \tan r}} \]  \hspace{1cm} (7)

Where

- \( N_1 \): Frequency constant of radial vibration (Hz-m)
- \( N_2 \): Frequency constant of lengthwise vibration (Hz-m)
- \( N_3 \): Frequency constant of longitudinal vibration (Hz-m)
- \( N_4 \): Frequency constant of thickness vibration (Hz-m)
- \( N_5 \): Frequency constant shear vibration (Hz-m)
- \( D \): Diameter of disc or column (m)
- \( l \): Length of plate, column, or cylinder (m)
- \( a,b \): Width of square plate or column (Hz-m)
- \( t \): Thickness of disc, square plate, or cylinder (m)

2) **Coefficient of electromechanical coupling**

The coefficient of electromechanical coupling represents the mechanical energy accumulated in a ceramic or crystal; it is related to the total electrical input. This coefficient \( k \) can be calculated for each individual vibration mode by using the resonant (\( fr \) or \( fm \)) and antiresonant frequencies (\( fa \) or \( fn \)) and the applicable formula shown here:

\[ K_r = \left( 0.395 \times \frac{fr}{fa} + 0.574 \right)^{-1} \]  \hspace{1cm} (6)

\[ K_{31} = \frac{r}{\sqrt{r - \tan r}} \]  \hspace{1cm} (7)

Where

- \( N_1 \): Frequency constant of radial vibration (Hz-m)
- \( N_2 \): Frequency constant of lengthwise vibration (Hz-m)
- \( N_3 \): Frequency constant of longitudinal vibration (Hz-m)
- \( N_4 \): Frequency constant of thickness vibration (Hz-m)
- \( N_5 \): Frequency constant shear vibration (Hz-m)
- \( D \): Diameter of disc or column (m)
- \( l \): Length of plate, column, or cylinder (m)
- \( a,b \): Width of square plate or column (Hz-m)
- \( t \): Thickness of disc, square plate, or cylinder (m)
3) Relative dielectric constant

When the electric flux density caused by applying an electric field \( E \) between electrodes of a transducer under a constant stress is regarded as \( D \), the relative dielectric constant is obtained by dividing the constant, defined by \( D/E = \varepsilon_T \), by the vacuum dielectric constant \( \varepsilon_0 \). This relative dielectric constant is expressed by \( \varepsilon_T \) when the direction of polarization and applied electric field are the same; it is expressed by \( \varepsilon_T \) when these directions are perpendicular.

Calculation of relative dielectric constant is shown in Eq. 11. Static capacitance is usually measured at 1kHz using an all-purpose bridge or a C meter.

\[
\varepsilon_T / \varepsilon_0 = \frac{1}{\varepsilon_0 S} \quad \text{(11)}
\]

(\( \varepsilon_T / \varepsilon_0 \) is also calculated using the same equation.)

Where
\( \varepsilon_0 \): Relative dielectric constant in vacuum (8.854x10^{-12} F/m)
\( t \): Distance between electrodes (m)
\( S \): Electrode area (m²)
\( C \): Static capacitance (F)

4) Young's modulus

For different modes of vibration, Young's modulus is calculated by Eq. 12, based on the sonic velocity and density of the material.

\[
Y^T = \rho v^2 [N/m^2] \quad \text{(12)}
\]

Where
\( \rho \): Density (kg/m³)
\( v \): Sonic velocity (m/sec.)
\( N \): Newton

5) Mechanical Q

The mechanical Q is the "sharpness" of mechanical vibration at resonant frequency, and is calculated with Eq 13.

\[
Q_m = \frac{fa^2}{2\pi fr Zr C(fa^2 - fr^2)} \quad \text{(13)}
\]

Where
\( fr \): Resonant frequency (Hz)
\( fa \): Antiresonant frequency (Hz)
\( Zr \): Resonant resistance (Ω)
\( C \): Static capacitance (F)

Where a simpler method is called for, mechanical Q may be calculated with Eq. 14, using frequencies \( f_1 \) and \( f_2 \) which are each 3 dB from the resonant frequency.

\[
Q_m = \frac{fr}{fr - f_2} \quad \text{(14)}
\]

The values shown for material characteristics in this catalog are calculated using Eq. 13.

6) Piezoelectric constant

There are two types of piezoelectric constants, the piezoelectric strain constant and the coefficient of voltage output.

a) Piezoelectric strain constant

This is a measure of the strain that occurs when a specified electric field is applied to a material that is in the condition of zero stress. This constant is calculated with Eq. 15.

\[
d = k \sqrt{\frac{e^T}{\varepsilon}} (m/V) \quad \text{(15)}
\]

Where
\( k \): Coefficient of electromechanical coupling
\( \varepsilon_T \): Dielectric constant
\( Y^T \): Young's modulus (Newton/m²)
b) Voltage output constant

This is the intensity of the electric field caused when a specified amount of stress is applied to a material that is in the condition of zero displacement. Voltage output constant is calculated with Eq. 16.

\[ g = \frac{d}{\varepsilon} (V \cdot m/N) \]  \hspace{0.5cm} (16)

Constants d and constants g can be \( d_{31}, d_{33}, \) or \( d_{15}, \) and \( g_{31}, g_{33}, \) or \( g_{15}, \) depending on the type of vibration.

7) Curie temperature

This is the temperature at which polarization disappears and the piezoelectric qualities are lost. It is also the temperature at which the value of the dielectric constant becomes maximum.

8) Temperature coefficient

The temperature coefficient is a measure of the variation of the resonant frequency and static capacitance with change in temperature. Temperature coefficient is calculated with Eqs. 17 and 18.

\[ TK(f) = \frac{1}{\Delta t} \cdot \frac{f(t_2) - f(t_1)}{f_0} \cdot 10^6 \text{(PPm/°C)} \]  \hspace{0.5cm} (17)

\[ TK(C) = \frac{1}{\Delta t} \cdot \frac{C(t_2) - C(t_1)}{C_{20}} \cdot 10^6 \text{(PPm/°C)} \]  \hspace{0.5cm} (18)

Where

- \( TK(f) \): Temperature coefficient of resonant frequency (PPm/°C)
- \( f(t_1) \): Resonant frequency at temperature \( t_1 \) (Hz)
- \( f(t_2) \): Resonant frequency at temperature \( t_2 \) (Hz)
- \( f_0 \): Resonant frequency at temperature 20°C (Hz)
- \( TK(C) \): Temperature coefficient of static capacitance (PPm/°C)
- \( C(t_1) \): Static capacitance (F) at temperature \( t_1 \) °C
- \( C(t_2) \): Static capacitance (F) at temperature \( t_2 \) °C
- \( C_{20} \): Static capacitance at 20°C (F)
- \( \Delta t \): Temperature difference \( (t_2 - t_1) \) (°C)

9) Aging rate

The aging rate is an index of the change in resonant frequency and static capacitance with age. To calculate this rate, after polarization the electrodes of a transducer are shorted together, and are heated for a specified period of time. Measurements are taken of the resonant frequency and static capacitance every 2 days. (That is, at 1, 2, 4, and 8 days.) The aging rate is calculated with Eq. 19.

\[ (AR) = \frac{1}{\log t_2 - \log t_1} \cdot \frac{X_{t_2} - X_{t_1}}{X_{t_1}} \]  \hspace{0.5cm} (19)

Where

- \( (AR) \): Aging rate for resonant frequency or static capacitance
- \( t_1,t_2 \): Number of days aged after polarization
- \( X_{t_1},X_{t_2} \): Resonant frequency or static capacitance at \( t_1 \) and \( t_2 \) days after polarization

10) Density

The density is calculated with Eq. 20, after determining the volume and weight of the specified ceramic material.

\[ D = \frac{W}{V} \text{(kg/m}^3) \]  \hspace{0.5cm} (20)

Where

- \( W \): Weight (kg) of ceramic material
- \( V \): Volume (m³) of material
NEPEC® NPM Ceramics

Characteristics of Standard Materials

Table 1-1 shows the material characteristics of TOKIN's standard NEPEC® NPM ceramics. Non-standard materials that are not listed in table 1-1 are available. Please contact us for further information.

Notes
1. Frequency constants;
   N1: Radial frequency constant (fr×D)
   N2: Lengthwise frequency constant (fr×l)
   N3: Longitudial frequency constant (fa×l)
   N4: Thickness frequency constant (fa×t)
   N5: Shear frequency constant (fa×l)
2. The temperature and aging characteristics shown are values of radial vibration for a sample of 17.7φ×1.0t (mm) in size.
3. The values of Kr (electromechanical coupling coefficient) shown in parentheses are approximate values. All others are exact.
4. Vibration limit speed:
   Please refer to page 14 for the detail.
5. A tensor symbol of each parameter is below.

**Limit of Vibration Speed**

Vibration energy of piezoelectric transducer is shown as \( P = \frac{1}{2} M v^2 \), ( i.e. \( M \)=Mass, \( v \)=Vibration speed.)

The large vibration energy can vibrate larger object such as ultrasonic cleaning equipment.

In general, the piezoelectric transducer generates heat as the displacement increases. The heat constraints the displacement. Our new material N85 can provide larger displacement at 0.5V or higher voltage compared with the displacement of the N6 material. Please refer to Fig. 3-1.

Sample dimension: 12 × 3 × 1 mm

Driving condition: Apply continuous sine wave signal at resonance frequency.

Definition of resonance frequency: The frequency where phases (time) of the operating voltage and the current overlaps.

![Vibration direction](image)

**Fig. 3-1 Heat generation in driving voltage (N6 vs. N85)**

In addition, N85 material can supply larger vibration energy compared with N6 material because the heat generation of the N85 material is smaller than the heat generation of the N6 material given a same displacement value.

The vibration velocity can be used as an index of material performance rather than displacement value because it shows how the material behaves under different conditions such as different shapes and different frequencies. The vibration speed, \( v_{max} \), is specified as a performance index for vibration energy when self heat generation is 20 degree C in Fig 3-2 below.

![Vibration speed](image)

**Piezoelectric Ceramics VOL.05**

18
Applications

The job of a transducer is to convert electrical energy into mechanical energy, and vice versa. And transducers using TOKIN piezoelectric ceramics are uniquely suited to performing this job in a wide variety of applications. To help classify transducers, we divide their applications into two general areas:
1) conversion of electrical energy into mechanical energy for hydraulic or motive power, and
2) converting mechanical energy into electrical energy for communications and electronics.

Langevin Bolt-On Transducers
Transducers for Cleaning Equipment
Transducers for Ultrasonic Motor
Piezoelectric Bimorph Actuators
Multilayer Piezoelectric Actuators
Molded Waterproof Transducers
High-Frequency Transducers
Aerial Microphone Transducers
Sonar Transducers
Langevin Bolt-on Transducers

Outline
TOKIN’s Langevin-type transducers are used where powerful ultrasonic waves must be generated, such as in cleaning equipment, ultrasonic treatment machines, and welders for plastic. For application flexibility and ease of installation, these transducers are mounted in a structure that can be bolted almost anywhere.

TOKIN’s high-performance NEPEC® N-61 is excellent for use in these Langevin transducers. TOKIN produces a number of this type of transducer, all featuring high quality and excellent output levels, and all based on a unique TOKIN design.

Features
• High mechanical Q and excellent electro-acoustic conversion efficiency, providing a high output amplitude.
• Piezoelectric element offers a high speed of vibration
• N-61 ceramics have extended temperature range, ensuring good amplitude linearity.
• Bolt-on mounting gives fast, easy installation and high reliability.

Markings
Product models are classified as shown in the example here:

NBL 45 28 2 H

H = Horn construction; output surface has step or horn shape.
S = Straight construction
2 = Number of piezoelectric elements (2 elements)
28 = Resonant frequency (28kHz)
45 = Diameter of acoustic wave radiation (φ 45mm)

Transducers for Cleaning Equipment

Outline
In the past, transducers for cleaning equipment have been found almost exclusively in ultrasonic cleaners for industrial and business use. Today, however, small cleaning equipment for glasses, false teeth, gemstones, etc. is increasingly found in individual households as well. TOKIN’s transducers for cleaning equipment utilize our N-6 material, providing ultrasonic generators that are compact and extraordinarily temperature-resistant.

Fig. 5-7 Variation in N-6 Characteristics with Temperature
Transducers for Ultrasonic Motor

Outline
The moving principal of ultrasonic motor is shown in Fig. 5-8. Piezoelectric actuator that is crimped with an elastic vibrator (stator) generates high-order bending vibration on the surface of the stator. A traveling wave is generated by excitation of the stator vibration. A slider and the stator are cramped together with high pressure and the slider is rotated by friction force at contact point of the stator.

Feature
Following is feature compare with conventional electromagnetic motor
- Simple structure with nonmagnetic material
- High static torque
- Precise positioning
- Quick response and high torque in all rotation speed

Ceramic material of Ultrasonic motor
Following material characteristics are required for the ultrasonic motor.
- Low loss factor → High Q hard material
- Large displacement by increase number of rotation → High Vmax value.
- Generates high rotation with low voltage → High electromechanical coupling factor K31
Piezoelectric Bimorph Actuators

Outline
A bimorph element has two bonded piezoelectric ceramic plates that are poled in thickness direction and expand/contract in length direction. It bends when one plate expands and another plate contracts. It is used for actuator and sensor applications as relatively large displacement can be obtained.
TOKIN can develop custom bimorph elements from bonded type bimorph to co-fired type bimorph that does not use organic glue.

Feature
- Simple Structure and production
- Large Displacement with Low Operating Voltage
- Low Operation Noise

Application
- Piezo Valves
- Flow Sensors
- Acoustic Devices (Speakers)
- Piezo Fans and etc.

Fig. 5-9 Structure of Piezo Bimorph
Multilayer Piezoelectric Actuators

Outline
Multilayer piezoelectric actuators are co-fired ceramic elements for converting electrical energy into mechanical energy such as displacement or force by utilizing the piezoelectric longitudinal effect. TOKIN’s multilayer piezoelectric actuators are produced based on our unique element structure design by making use of originally developed piezoelectric ceramic material with high electrostrictive factors. Compared to conventional piezoelectric actuators, they are smaller in size but can generate higher displacement and force at low voltages. AE-series actuators that is resin coated version feature compact size and wide variety in shape for use un ultra-fine positioning mechanisms and drive sources for various application.
The metal sealed ASB, ASL and AHB series actuators are much less influenced by ambient humidity because of insulation from the atmosphere. As a result, long service life and high performance never experienced of in the past have been attained to allow use in various application such as semiconductor device production equipment and optocal communication equipment requiring high reliability.

Application
* Image stabilization of DSC, Auto focus of camera, Precision positioning, Linear motors, Pumps, Valves, Vibration source, Vibration suppression, Sensor, Position control of optical system, Manipulators, AFM, Printer, X-Y stage of a stepper and etc.

Feature
AE Series:
* Large generated force
* High-speed response
* Accurate positioning
* Low power consumption
* Very small size

ASB, ASL and AHB Series
* High reliability
* Easier installation with built-in pre-load mechanism and mounting attachment
* Minimum mechanical abrasion
* Large generated force
* Accurate positioning

TOKIN’s multilayer piezoelectric actuators are available in four series. For the detail information, please refer to a catalogue of "Multilayer Piezoelectric Actuators".

<table>
<thead>

**Precautions**
- All specifications in this catalog and production status of products are subject to change without notice. Prior to the purchase, please contact TOKIN for updated product data.
- Please request for a specification sheet for detailed product data prior to the purchase.
- Before using the product in this catalog, please read "Precautions" and other safety precautions listed in the printed version catalog.
Molded Waterproof Transducers

Outline
Transducers that can withstand salt water and underwater pressures are used to generate ultrasonic signals for fish finders, sonar equipment, depth gauges, and Doppler-effect velocity and current meters.

TOKIN’s molded transducers are highly reliable, even in the face of severe underwater conditions. Completely waterproof, they offer excellent mechanical strength and temperature characteristics, thanks in part to their unique TOKIN design and technology. By using a variety of different materials for our molded transducers, we can offer a large variety of frequency, input, and directivity characteristics.

Features
- High reliability, thanks to TOKIN's own molding technology, including solid urethane rubber molding and baked neoprene rubber.
- Excellent noise characteristics.
- Wide range of frequencies and molding materials available.

Note: Transducers with non-standard shapes and dimensions are also available. For inquiries, see page 34.
High-Frequency Transducers

Outline

Compared to ordinary piezoelectric transducers, these types operate at much higher frequencies: usually in the 1~10 MHz range. One of the primary applications of high-frequency transducers is as a sensor for flaw detection. Another important application area is medical equipment; in fact, with ultrasonic diagnosis becoming ever more widespread, HF piezoelectric transducers are the focus of increasing attention.

Here are some of the types of ultrasonic diagnosis that require HP transducers:

- Doppler system:
  - Fetus phonocardiographs
  - Blood flowmeter
- Pulse echo system:
  - Tomography
  - Electronic scanning
  - Mechanical scanning
  - Cranial disease diagnosis
  - Cardiac wall displacement measurement

The vibration mode of these transducers is usually thickness resonance, and the frequency is high. For this reason, thin plate transducers with low impedance at resonance are needed. The dielectric constant of TOKIN NEPEC® is low, and its impedance characteristics and other performance parameters are excellent for use in high-frequency transducers.

Features

- High impedance at resonant frequency.
- Excellent electromechanical coupling in thickness vibration mode.
- High sensitivity.
- Both thickness and radial vibration offer good anisotropic properties.
- Thickness resonance spurious emissions are low, and resolution is excellent.

Aerial Microphone Transducers

Outline

Ultrasonic aerial microphones generate ultrasonic waves that are radiated through the air and reflected from a target to measure distance. These microphones are used for traffic control, obstacle detection, robot sensors, and other similar applications.

There are two types of aerial microphone with different vibration modes, bimorph type and cylindrical type. Such transducers are most often used together with a horn mounted in the radiation plane. TOKIN aerial microphone transducers have good output power, receiving sensitivity and directivity—all important in this type of application.

Features

- Good temperature characteristics.
- Cylindrical transducers are moisture-resistant, ensuring stable operation outdoors.
- High mechanical coupling, high sensitivity.

Sonar Transducers

Outline

Depth finders, underwater detectors, and fish finders all utilize the principle of sonar, in which sound waves are radiated through the water to detect and measure the distance to the target. Although there are differences in the resolution and distance capabilities required of sonar transducers, in general all should have the best possible sensitivity, resolution, directivity, and reliability. Sonar transducers fabricated of TOKIN's superior NEPEC® material score high marks in all departments, and are available for a wide variety of applications.

Precautions

- The names of the products and the specifications in this catalog are subject to change without notice for the sake of improvement. The manufacturer also reserves the right to discontinue any of these products. At the time of delivery, please ask for specification sheets to check the contents before use.
- Material selection, installation and activation of piezoelectric ceramics should be decided upon by users according to the application. For proper evaluation and decision, products should be tested repeatedly in both realistic and abnormal operating conditions.
- The manufacturer’s warranty will not cover any disadvantage or damage caused by improper use of the products, deviating from the characteristics, specifications, or conditions for use described in this catalog.
- Please be advised that the manufacturer accepts no responsibility for any infraction on third party patents or industrial copyrights by users of the manufacturer’s products. The manufacturer is responsible only when such infractions are attributable to the structural design of the product and its manufacturing process.
- No part of this document may be reproduced without written permission from the manufacturer.

Export Control

For customers outside Japan
TOKIN products should not be used or sold for use in the development, production, stockpiling or utilization of any conventional weapons or mass-destructive weapons (nuclear weapons, chemical or biological weapons, or missiles), or any other weapons.

For customers in Japan
For products which are controlled items subject to the 'Foreign Exchange and Foreign Trade Law' of Japan, the export license specified by the law is required for export.

When ordering NEPEC Piezoelectric Materials
Specify the following items when placing an order with TOKIN for NEPEC:
1) Shape (disc, column, cylinder, square plate, sphere, or bimorph).
2) Desired material and application.
3) Dimensions.
4) Vibration mode and resonant frequency used.
5) Whether special surface treatment is required, and if so, what type.
6) S, P, or other designated terminal.

When ordering transducers or other finished products
Specify model name and number when placing an order for transducer products such as molded transducers for underwater use. Also note any special requirements.

This catalog is current as of September 2013.
